Mode of Operation

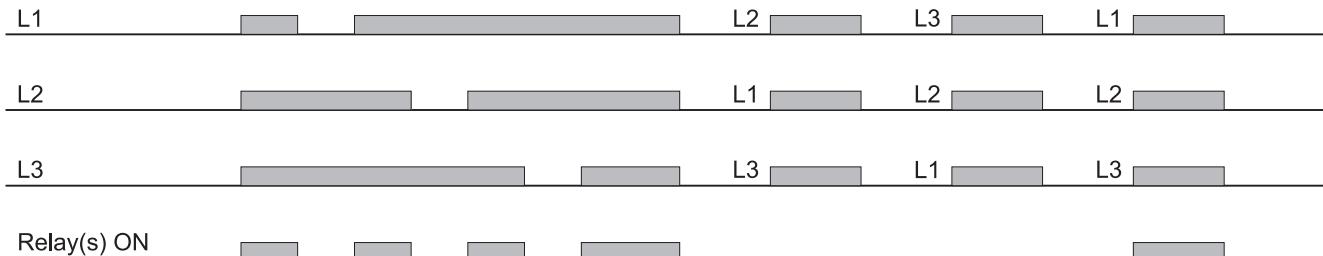

DPA51 monitors its own 3-phase power supply voltage. The relay operates when all the phases are present and the phase sequence is correct. The relay releases when one phase-phase voltage drops

below 85% of the other phase-phase voltages or when the phase sequence is wrong.

Example 1
The relay monitors that the power supply has the correct phase sequence and that all phases are present.

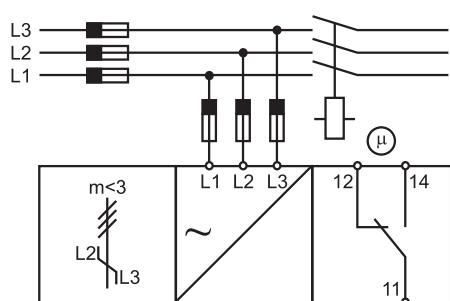

Example 2
The relay releases in case of interruption of one or more phases, provided that the regenerated voltage does not exceed 85% of the phase-phase voltage.
